

rrnoise under three memory configurations: the same groups regress every time

Whole-model totals: Sram_Only +3,015, Shared_Sram +15,075, Dedicated_Sram +19,060 cycles.

27 of 29 groups keep the same direction in all three modes; no group flips between improvement and regression.

Bar shade darkens from Sram_Only to Dedicated_Sram. Only groups that move in at least one configuration are drawn. Every memory mode compiles to a different artifact, so memory-system behaviour and compiler-generated program change remain NOT_SEPARATED: this is a configuration intervention, not a bandwidth intervention.
