

Which structural metrics survived a change of Corstone platform

Same NPU, same MAC configuration, byte-identical Vela artifact; only the host platform changes.

CLASS A holds timing-adapter state constant (SSE-310 ↔ SSE-315). CLASS B does not. The classes are never pooled.

The only disagreements are eight threshold scaling-class labels, all in CLASS B, every one PARTIAL on the TA_ON side and STRONG on the TA_OFF side — crossings of the frozen 0.75 cut point. No ranking, direction or saturation verdict changed anywhere.

In CLASS B the timing-adapter state, the subsystem and the Fast Models implementation change together: the disagreements are ASSOCIATED_WITH those comparisons, never attributed to one factor.
