

Ethos-U85 256 → 512 MACs: per-operation-group cycle change for rnnoise

Ten groups regress, one improves, three are unchanged. No single group accounts for the reversal — the largest is about a fifth of it.

whole-model observed delta	+19,000
reconstructed profiled-group delta	+19,060
residual	60

deterministic profiling-boundary (interrupt-service) residual — the two boundaries are not identical

Groups are the frozen common attribution partition: where small operations merge into one interrupt-service window, only the group effect is evaluable, not per-operation cause. Bars show where cycles moved, not why — no group is claimed as the cause of the whole-model reversal.
